The oxetane ring is a notable structural feature in natural products and is present in a large panel of synthetic molecules used in drug discovery.¹ Interestingly, this oxygenated four-membered ring scaffold is also a high-value intermediate in organic synthesis for further chemical modifications due to its inherent ring strain. Among the different approaches for its preparation, the photochemical [2+2]-Paterno-Büchi reaction is arguably the most useful synthetic method.²

Inspired by our own research on photochemical transformations,³ we decided to study this photochemical [2+2]-cycloaddition reaction between electron-rich alkenes and photo excited carbonyl derivatives in two parallel objectives. The first one focuses on the total synthesis of a natural product with the development of an efficient gram-scale preparation of the all four stereoisomers of oxetin.⁴ The second project involving an oxetane intermediate concerns the synthesis of fused bicyclic oxetanol scaffolds and investigations of their post-functionalizations, such as hydrogenolysis and acid-rearrangements.⁵
